ASSIGNMENT III, Dec 18

Due date: Jan, 17th, 2020 h00:00

In this assignment you are requested to choose 1 among the proposed exercises, and to implement either an MPI or an OpenMP code.

The mark corresponding to each code is stated in the exercises description.

We remind you that this assignment counts for the 30% of the final mark.

Taking into account the fact that we have not yet covered the topic of hybrid MPI + OpenMP codes, but also that it is almost straightforward if no MPI call is made from within a multi-thread region, we encourage you to try that on the code you choose *once you have completed the assignment*.

This optional part will be rewarded, if correctly - or in any case somehow brilliantly - accomplished, by additional points (at most 10).

EXERCISE 1

The Mandelbrot set

In this exercise, you are required to implement a parallel code that check the condition [1] for a given section of the complex plane (or, in other words, that computes the Mandelbrot set).

The Mandelbrot set is generated on the complex plane \mathbb{C} by iterating the complex function $f_c(z)$ whose form is

$$f_c(z) = z^2 + c \quad (1)$$

for a complex point $c = x + iy$ and starting from the complex value $z = 0$ so to obtain the series

$$z_0 = 0, z_1 = f_c(0), z_2 = f_c(z_1), \dots, f_c^n(0) \quad (2)$$

The *Mandelbrot Set* \mathcal{M} is defined as the set of complex points c for which the above sequence is bounded. It may be proved that once an element i of the series is more distant than 2 from the origin, the series is then unbounded. Hence, the simple condition to determine whether a point c is in the set \mathcal{M} is the following

$$|z_n = f_c^n(0)| < 2 \text{ or } n > I_{max} \quad (3)$$

where I_{max} is a parameter that sets the maximum number of iteration after which you consider the point c to belong to \mathcal{M} .

Given a portion of the complex plane, included from the bottom left corner $c_L = x_L + iy_L$ and the top right one $c_R = x_R + iy_R$, an image of \mathcal{M} , made of $n_x \times n_y$ "pixels" can be obtained deriving, for each point c_i in the plane, the sequence $z_n(c_i)$ to which apply the condition (3), where

$$\begin{aligned} c_i &= (x_L + \Delta x) + i(y_L + \Delta y) \\ \Delta x &= (x_R - x_L)/n_x \\ \Delta y &= (y_R - y_L)/n_y. \end{aligned}$$

In practice, you define a 2D matrix `M` of integers, whose entries `M[j][i]` correspond to the image's pixels. What pixel of the complex plane \mathbb{C} corresponds to each element of the matrix depends obviously on the parameters $(x_L, y_L), (x_R, y_R), n_x$, and n_y .

Then you give to a pixel `M[j][i]` either the value of 0, if the corresponding c point belongs to \mathcal{M} , or the value n of the iteration for which

$$|z_n(c)| > 2 \quad (4)$$

(n will saturate to I_{max}).

This problem is obviously embarrassingly parallel, for each point can be computed independently of each other and the most straightforward implementation would amount to evenly subdivide the plane among concurrent processes (or threads). However, in this way you will possibly find severe imbalance problems because the \mathcal{M} 's inner points are computationally more demanding than the outer points, the frontier being the most complex region to be resolved.

A correct version, either in MPI or in OpenMP, of the straightforward implementation will still be considered a valid solution of this exercise, but worth a maximum of **27 points**.

More sophisticated implementation, with a more balanced work distribution, that you have to conceive and implement, will be worth the full mark of **30 points**.

Requirements:

1. your code have to accept I_{max}, c_L, c_R, n_x and n_y as arguments. Specifically, the compilation must produce an executable whose execution has a proper default behaviour and accept argument as follows: `./executable n_x n_y x_L y_L x_R y_R I_max`
2. the size of integers of your matrix `M` shall be either `char` (1 byte; $I_{max} = 255$) or `short int` (2 bytes; $I_{max} = 65535$).
3. your code must produce a unique output file, using MPI I/O if you choose to implement the MPI version. The output must be in one of the 2 following format:
 - simple binary format, as follows: 4 double: x_L, y_L, x_r, y_R 3 integers (4 bytes long): n_x, n_y and I_{max} The exact dump in row-major order of the 2D matrix `M` that you have calculated.
 - you may **directly produce an image file** using the very simple format `.pgm` that contains a grey-scale image. You find a function to do that, and the relative simple usage instructions, in Appendix I at the end of this page. In this way you may check in real time and by eye whether the output of your code is meaningful.
4. you have to determine the strong and weak scaling of your code, accordingly to the choice of developing an MPI or OpenMP (or hybrid) version. The corresponding plots will be part of your report.

Note 1: Mandelbrot set lives roughly in the circular region centered on $(-0.75, 0)$ with a radius of ~ 2 .

Note 2: the multiplication of 2 complex numbers is defined as
 $(x_1 + iy_1) \times (x_2 + iy_2) = (x_1x_2 - y_1y_2) + i(x_1y_2 + x_2y_1)$

Exercise 2

N-Body code

The N-Body problem is representative of a large class of problems in scientific computing. It amounts to solve the evolution of a system of N interacting particles (we consider here a closed system, i.e. the only forces acting to the particles are due to the mutual interaction within the system itself).

Specifically, here you are required to solve the problem of an interaction that has a Coulomb potential

$$V(r) \propto \frac{e_1 \cdot e_2}{\|\mathbf{r}_1 - \mathbf{r}_2\|} \quad (5)$$

where \mathbf{r}_1 and \mathbf{r}_2 are the vector positions of 2 interacting particles whose charges are e_1 and e_2 respectively. In this exercise actually we do consider the gravitational problem, where only 1 charge type exists (the mass of the particle).

Hence, the mutual force between 2 particles is:

$$\mathbf{F}_{1,2} = G \frac{m_1 \cdot m_2}{\|\mathbf{r}_1 - \mathbf{r}_2\|^3} \cdot (\mathbf{r}_1 - \mathbf{r}_2) \quad (6)$$

from which you derive their mutual acceleration

$$\mathbf{a}_{1,2} = \mathbf{F}_{1,2} / m_{1,2}. \quad (7)$$

We are proposing you the *collisional* ¹ problem, i.e. to solve the interaction among true material bodies.

As such, the resultant force on a particle q is the summation of all the direct interactions with all the other particles:

$$\mathbf{F}_q = Gm_q \sum_{i=0, i \neq q}^N m_i \frac{(\mathbf{r}_1 - \mathbf{r}_2)}{\|\mathbf{r}_1 - \mathbf{r}_2\|^3} \quad (8)$$

Hence, the variation on velocity and positions in a given time step Δt are:

$$\begin{aligned} \Delta \mathbf{v}_q(t) &= \mathbf{v}_q(t) + \mathbf{a}_q(t) \cdot \Delta t \\ \Delta \mathbf{r}_q(t) &= \mathbf{r}_q(t) + (\mathbf{v}_q(t) + \Delta \mathbf{v}_q(t)) \cdot \Delta t \end{aligned} \quad (9)$$

Of course, *that is **not** a correct integration scheme* and if applied it would lead to a broadly wrong evolution. However, the focus here is not about the physically correct evolution of an N-body system, so we will stick to this integration scheme because of its simplicity.

Still for the sake of simplicity, you may consider to forget about real physical quantities. Use $G = 10^{-6}$ (to avoid too large accelerations) and *natural units*: in practice, do not worry about the fact that positions, velocities and accelerations are expressed in physical units, just consider them as pure numbers.

This exercise is worth at most 36 points. At most 10 additional points will be given for the implementation of *both* MPI and OpenMP versions. At most additional 10 points will be given for the implementation of anhybrid MPI+OpenMP version.

Requirements:

1. You shall generate the *initial conditions* (i.c. since now on) , i.e. the initial distribution of the particles in your computational domain: let's consider it is a cubic box of side 1. Then, your particles will be confined initially in the volume $[0 : 1] \times [0 : 1] \times [0 : 1] \in \mathbb{R}^3$ and they will be uniformly distributed in that volume. The main parameter for that is N_p , which is the total number of particle in your system. The total mass in your system is, instead, fixed to the value $M_{tot} = 100$ (then, your particle mass m varies with the particles number N_p).

The particles must have (at least) the following properties: a 3D position, a 3D velocity and an Energy.

The particle positions can be randomly distributed in the volume in a uniform way and will have the same mass $m = 1$ (so you can practically ignore the particles' mass). The single components of the 3D velocities (i.e. the values $\mathbf{v}_i = [v_x, v_y, v_z]_{i=1, \dots, N_p}$) must be randomly distributed with a Gaussian pdf centered on 0, having $\sigma = 0.01$. At this moment, particles' energy is set to the pure kinetic energy of the particle, $E_{i,kin} = 1/2 * m_i \cdot \|\mathbf{v}_i\|^2$.

We require that your code must be able to perform a **domain decomposition among MPI tasks**, even if your N-body code is implemented in OpenMP. Then there are two cases:

- you implement the N-Body code in OpenMP In this case, we require a separate MPI code that generates the initial conditions. In that code, all the N_T MPI tasks will generate a fraction N_p / N_T (note: you have to handle the remainder $N_p \bmod N_T$) of the particles and then all the tasks will cooperate to distribute them . In fact, for this task you will consider your computational domain as subdivided in N_T slices along one of the axis, so that the task T_i is responsible for the particles that live in the $i - th$ slice (see Fig. 1 here below) and must receive all of them and only them.

Fig. 1

After the i.c. generation, your code will write a file that contains the i.c. (see Note 2 about the format). Your OpenMP code will start reading the i.c. from a generic file (given as input argument) that has that same format. To write this file, either you use the MPI I/O, so that all the MPI tasks write on the same files, or a different approach (for instance, each MPI task writes its own file or every evenly numbered MPI task T_i writes a file with its data and the data of its neighbour task T_{i+1}). Whichever approach you choose, however, the reading of the file must be independent of the number of files in which the i.c. are splitted. In other words: if you choose to write a separate file for every MPI task, and you generate them with N_{T_1} tasks, then you must be able to read and distribute the i.c. when running with a different number of tasks N_{T_2} .

- you implement an MPI code In this case, the previously described code can be simply part of your code, and the i.c. generation and the domain decomposition can be the first phase of your run.
2. Once the i.c. have been generated (or read in), your code must enter in a loop in which the resultant force for each of the particles is determined, their new positions are calculated, and the new time-step is obtained with the constraint $\Delta t \leq \Delta t_{max}$ such that

$$\left| \frac{\Delta \mathbf{v}}{\mathbf{v}} \right|_{max} < \epsilon. \quad (10)$$

where ϵ is a parameter of your code (let's say of the order of ~ 0.05). Such a loop may have a form similar to

```
time      = 0;
delta_t   = delta_t_max;
for ( int iter = 0; iter < iter_max && time < time_max; iter++ )
{
    estimate_forces(delta_t);
    calculate_new_positions_and_energies(delta_t);

    update_total_system_energy()

    time    += delta_t;
    delta_t = obtain_new_delta_t();

    if( iter % time_to_write_a_checkpoint )
        write_a_checkpoint_file()
}
```

Let us comment on few points, to further simplify the problem:

- As for the design of the force estimation, you are allowed to assume that the total number of particle N_p will always be small enough that the whole system can reside in each of the MPI process ² (or, obviously, on a single node as for what concerns the OpenMP implementation). In fact, by reason of the collisional scaling $\sim O(N_p^2)$, N_p is typically at the scale of $N_p \lesssim 10^7$.
- The time-step Δt is the same for all the particles, i.e. it is a global time-step.
- For the purpose of this assignment, `iter_max` can be as small as 2, since the focus is not on the correct evolution of the gravitational system.
- As a consequence of the previous point. you can ignore the fact that while the system is evolving and the particles are moving, the domain decomposition should, in principle, be updated. Each MPI task, or OpenMP thread, will continue to update the particles it has been given after reading the i.c.

- The loop example shown above is indeed only an example. For instance, in your design, you may choose to merge the estimate of forces and the update of the positions and the energy.
- The energy of a particle i is the sum of its kinetic energy and its potential energy:

$$E_i = \frac{1}{2}m_i\|\mathbf{v}_i\|^2 + G \sum_{j=0, j \neq i}^{N_p} \frac{m_j}{\|\mathbf{r}_i - \mathbf{r}_j\|} \quad (11)$$

(G , m_i and m_j have been put in the formula for the sake of clarity)

Note 1: data structure a suitable C data structure could be the following:

```
typedef struct { double a[3]; } vect;
typedef struct { vect pos; vect vel; double E;} particle;

// pos is the 3D particle's position
// vel is the 3D particle's velocity
// E is the particle's energy
// mass is not needed, since all the particles are created equal
```

Note 2: format of the i.c. file

The i.c. file must be a binary file formatted as follows:

- 1 integer (4 bytes): the floating-point precision of the data in the file, expressed in bytes (i.e. either 4 or 8)
- 1 integer (4 bytes): the number of particles in the file
- 1 integer (4 bytes): the number of files in which the file is splitted (if you write the file using separate files for each MPI task, that may help the reconstruction).
- 1 double: the time of the file (0 for the i.c., the evolution time for the checkpoint files)
- all the particles in sequence: 7 floating points for each of them (3 for the position, 3 for the velocity and 1 for the energy). No particular order among the particles is required.

Appendix I

Writing a **PGM** image

The **PGM** image format, companion of the **PBM** and **PPM** formats, is a quite simple and portable one. It consists in a small header, written in ASCII, and in the pixels that compose the image written all one after the others as integer values. A pixel's value in **PGM** corresponds to the grey level of the pixel. Even if also the pixels can be written in ASCII format, we encourage the usage of a binary format.

The header is a string that can be formatted like the following:

```
printf( "P5\n%d %d\n%d\n", width, height, maximum_value );
```

where “P5” is a magic number, `width` and `height` are the dimensions of the image in pixels, and `maximum_value` is a value smaller than 65536. If `maximum_value < 256`, then 1 byte is sufficient to represent all the possible values and each pixel will be stored as 1 byte. Instead, if `256 <= maximum_value < 65536`, 2 bytes are needed to represent each pixel (that is why in the description of Exercise 1 we asked you that the matrix `M` entries should be either of type `char` or of type `short int`).

In the sample file `write_pgm_image.c` that you find the `Assignment03` folder, there is the function `write_pgm_image()` that you can use to write such a file once you have the matrix `M`.

In the same file, there is a sample code that generate a square image and write it using the `write_pgm_image()` function. It generates a vertical gradient of $N_x \times N_y$ pixels, where N_x and N_y are parameters. Whether the image is made by single-byte or 2-bytes pixels is decided by the maximum colour, which is also a parameter. The usage of the code is as follows

```
cc -o write_pgm_image write_pgm_image.c
./write_pgm_image [ max_val] [ width height]
```

as output you will find the image `image.pgm` which should be easily rendered by any decent visualizer .

Once you have calculated the matrix `M`, to give it as an input to the function `write_pgm_image()` should definitely be straightforward.

1. as opposed to the *collisionless* problem, where the “particles” are actually a sample of the matter distribution in space and not real bodies

2. That would be dreadfully wrong for a collisionless simulation, since the complexity of those problem scales as $\sim O(N_p \log(N_p))$ and a considerable number of particles is routinely used for those simulations (as large as $\sim 10^{10}$)
